Identification and Treatment of Major Depressive Disorder (MDD) for Adults

Purpose
To improve the identification and treatment of adult patients with Major Depressive Disorder (MDD) in the primary care setting. Persistent Depressive Disorder, formerly known as Dysthymic Disorder, Seasonal Affective Disorder and Bipolar Disorder, are not considered to be the focus of this guideline.

Key Points

- Approximately one in eight patients in primary care settings meet current MDD criteria.
- Untreated depression may interfere with recovery from co-morbid conditions and increase the chance of death, for example post MI or CVA.
- MDD is treatable: expect one-third of patients to remit with first anti-depressant trial, but up to 75% can achieve remission with subsequent interventions and properly applied medication management.
- Mild to moderate depression may be treated by medication and/or psychotherapy, typically more severe depression requires medication or other somatic treatments.
- Adequate dosing of antidepressant medication, patient adherence with medication and/or psychotherapy are keys to favorable outcomes.
- Remission is the goal of treatment.
  - Patients not treated to remission of symptoms by 3 months are nearly 3 times more likely to have a relapse/recurrence at long-term follow-up.
  - Patients who achieve remission have the best outcomes including lower risk of relapse and occurrence of suicidal behaviors.
- Continuation phase antidepressant treatment for 9-12 months after remission prevents early recurrence.
- Decisions about the maintenance phase of antidepressant treatment depend upon whether this is a 1st, 2nd or 3rd or more episode and other factors including whether there are warning signs before an episode, the severity of the episode, presence of psychosis, level of functioning and the insight of the individual.
- Use of antidepressants in Bipolar Disorder is controversial, and should generally be avoided when possible. Antidepressants appear to increase the risk of rapid cycling and induction of mania, particularly in the Bipolar I subtype. When used, a mood stabilizing agent should be in place to protect against mood destabilization. For more information see International Conference on Bipolar Disorder Task Force Guidelines of Antidepressant Use in Bipolar Disorder.

Quality Measures Commonly Used by National Organizations

- Suicide Risk Assessment Completed: Percentage of adult patients with a new diagnosis or recurrent episode of MDD who had a suicide risk assessment completed at each visit during the measurement period. (PQRS/CMS Meaningful Use – See References on page 13 in MDD Guideline for more information.)
- Antidepressant Medication Management Optimized: Percentage of adult patients who were diagnosed with a new episode of major depression, treated with antidepressant medication, and who remained on antidepressant medication treatment for at least 180 days (6 months). (CMS Meaningful Use)
- Use of PHQ-9 in Assessment and Management: Adult patients age 18 and older with the diagnosis of major depression or dysthymia who have a PHQ-9 tool administered at least once during a 4 month period in which there was a qualifying visit. (CMS Meaningful Use)
- Remission at Twelve Months by PHQ-9 Criteria: Adult patients age 18 and older with major depression or dysthymia and an initial PHQ-9 score >9 who demonstrate remission at twelve months defined as PHQ-9 score less than 5. This measure applies to both patients with newly diagnosed and existing depression whose current PHQ-9 score indicates a need for treatment. (CMS Meaningful Use)
Identification and Treatment of Major Depressive Disorder (MDD) for Adults

High Risk Populations/Disparities

- Depression affects twice as many women as men, regardless of racial and ethnic background or income.
- Suicide among males is four times higher than among females and represents 79% of all U.S. suicides. Depression is one of the most common conditions associated with suicide in older adults, but it is not always recognized and is often undertreated.
- African Americans are treated for depression less often than Caucasians; however, they are 40% more likely to experience depression than Caucasians or Hispanics.
- Poverty and low socioeconomic status contribute to depression.
- Medical conditions can contribute to depressive symptoms. For example, CAD, diabetes, chronic pain, dementia, cancer, HIV/AIDS, trauma, obesity, pregnancy/postpartum, chronic medical/psychiatric conditions.
- Research has demonstrated that certain factors increase the risk of depression. These include: age, gender, family history, stress (i.e., marital problems, divorce, death of loved one, unemployment) and emotional trauma.
## Identification and Treatment of Major Depressive Disorder (MDD) for Adults

### Common Presentation
- Unexplained pain complaints
- Low energy
- Apathy, irritability, anxiety
- Sexual complaints
- Disrupted sleep patterns
- Vague GI symptoms
- Appetite changes
- Social avoidance
- Headaches

### Assess Family History
First degree relatives with MDD, Bipolar Disorder and/or Suicidal Behavior

### Suicide and Violence Assessment
Does your patient have the...
- Thoughts
- Intent
- Plan
- Means (including access to firearms)
- Behavior

...indicating risk to himself/herself and/or others

### National Suicide Prevention Lifeline
Statewide 24/7
800-273-TALK (8255)
TTY line: 800-799-4889

### Rochester Community Mobile Crisis Team
585-275-5151 or (800) 310-1160
TTY line: 585-275-2700
On-call response available after hours
Mon-Fri, 8:30am-10:00pm
Weekends and Holidays, 10:00am-6:30pm
Referrals can be made 24 hours a day, 365 days of the year.

In an emergency, contact one of the psychiatric ERs for guidance:
- RGH Crisis Intervention Unit: 585-922-3728
- SMH: 585-275-4501
- Unity: 585-368-3950

### Screen for MDD using 2 Question Screen
During the past month, have you been bothered by:
1. Little interest in doing things AND/OR
2. Feeling down, depressed or hopeless

### Use of a rating scale can aid in diagnosis, severity rating, and tracking responses to treatment. This guideline refers to one such measurement based tool, the PHQ-9.

### Assess Suicide and Violence Risks
Assess for Psychotic Features

### Rule Out Medical Mimics of MDD
Guided by history, exam and risk factors

### Rule Out Bipolar Disorder
Inquire about history of mania or hypomania

### Guidelines are intended to be flexible. They serve as reference points or recommendations, not rigid criteria. Guidelines should be followed in most cases, but there is an understanding that, depending on the patient, the setting, the circumstances, or other factors, care can and should be tailored to fit individual needs.

When to Consider Referring to a Mental Health Specialist

- Higher suicide potential
- Psychotic symptoms
- Lack of response to treatment
- Need for psychotherapy/counseling
- Higher level of severity
- Active co-occurring substance abuse
- Poor adherence/compliance
- Diagnostic uncertainty
- Management uncertainty
- Electroconvulsive therapy (ECT)
- High level of depression
- Patient or family request
- Complex cultural considerations
- Presence of significant psychosocial stressors or interpersonal difficulties

ACUTE PHASE TREATMENT 1-3 months

Our Mission is Remission defined as a PHQ-9 <5

Patients who fail to achieve remission are more likely to have functional impairment, chronic symptoms, recurrence and suicidal behavior.

CONTINUATION PHASE TREATMENT 9-12 months after remission

All patients who remit on medication should continue medication at the same dose that achieved remission for 9-12 months before considering discontinuation.

MAINTENANCE PHASE TREATMENT 12 months +

All patients who have 3 or more lifetime episodes are candidates for maintenance antidepressant treatment. Some clinical situations and patient choice may argue for maintenance treatment.
Patient Health Questionnaire (PHQ-9)*

PHQ-9 Scoring Card for Severity Determination

For healthcare professional use only

Scoring – add up all checked boxes on PHQ-9

For every “√”:
“Not at all” = 0; “Several days” = 1; “More than half the days” = 2; “Nearly every day” = 3

Interpretation of Total Score

<table>
<thead>
<tr>
<th>Total Score</th>
<th>Depression Severity</th>
</tr>
</thead>
<tbody>
<tr>
<td>1-4</td>
<td>Minimal depression</td>
</tr>
<tr>
<td>5-9</td>
<td>Mild depression</td>
</tr>
<tr>
<td>10-14</td>
<td>Moderate depression</td>
</tr>
<tr>
<td>15-19</td>
<td>Moderately severe depression</td>
</tr>
<tr>
<td>20-27</td>
<td>Severe depression</td>
</tr>
</tbody>
</table>

To monitor severity over time for newly diagnosed patients or patients in current treatment for depression:

1. Patients may complete questionnaires at baseline and at regular intervals (e.g., every 2 weeks) at home and bring them in at their next appointment for scoring or they may complete the questionnaire during each scheduled appointment.

2. Add up √s by column. For every √:
   “Several days” = 1; “More than half the days” = 2; “Nearly every day” = 3

3. Add together column scores to get a TOTAL score.

4. Refer to the accompanying PHQ-9 Scoring Card to interpret the TOTAL score.

5. Results may be included in patients’ files to assist you in setting up a treatment goal, determining degree of response, as well as guiding treatment intervention.

6. If a positive response on Question #9, conduct additional suicide risk assessment. It should be determined/distinguished whether the patient is conveying passive thoughts that he/she would be better off dead or active thoughts of self harm.

*Copyright held by Pfizer Inc., but may be photocopied for use in a clinical setting
A Selection of Medical Conditions that May Mimic MDD

Workup for medical mimics is based on clinical history, exam and known risk factors to rule out medical causes for patients presenting with depression. Laboratory tests to consider: complete blood count, comprehensive metabolic panel, thyroid-stimulating hormone, and urinalysis.

*The role of vitamin D deficiency and depressive disorder remains uncertain.

Guidelines are intended to be flexible. They serve as reference points or recommendations, not rigid criteria. Guidelines should be followed in most cases, but there is an understanding that, depending on the patient, the setting, the circumstances, or other factors, care can and should be tailored to fit individual needs.

Manic and Hypomanic Episodes

The focus is to treat major depressive disorder, which requires ruling out bipolar manic or hypomanic episodes.

Manic Episode
- A distinct period of abnormally and persistently elevated, expansive, or irritable mood and abnormally and persistently increased goal-directed activity or energy, lasting at least 1 week and present most of the day, nearly every day (or any duration if hospitalization is necessary).
- During the period of mood disturbance and increased energy or activity, three (or more) of the following symptoms have persisted (four if the mood is only irritable) and have been present to a significant degree and represent a noticeable change from usual behavior:
  1. inflated self-esteem or grandiosity
  2. decreased need for sleep (e.g., feels rested after only 3 hours of sleep)
  3. more talkative than usual or pressure to keep talking
  4. flight of ideas or subjective experience that thoughts are racing
  5. distractibility (i.e., attention too easily drawn to unimportant or irrelevant external stimuli), as reported or observed
  6. increase in goal-directed activity (either socially, at work or school, or sexually) or psychomotor agitation (i.e., purposeless non-goal-directed activity)
  7. excessive involvement in activities that have a high potential for painful consequences (e.g., engaging in unrestrained buying sprees, sexual indiscretions, or foolish business investments)
- The mood disturbance is sufficiently severe to cause marked impairment in occupational functioning or in usual social activities or relationships with others, or to necessitate hospitalization to prevent harm to self or others, or there are psychotic features.
- The symptoms are not due to the direct physiological effects of a substance (e.g., a drug of abuse, a medication, or other treatment) or a general medical condition (e.g., hyperthyroidism).

Hypomanic episode
- Minimum of four day period of elevated, expansive, or irritable mood and abnormally and persistently increased activity or energy with three or more (four if mood is only irritable) manic symptoms lasting at least 4 consecutive days and present most of the day, nearly every day.
- Not severe enough to cause marked impairment socially or occupationally, without psychosis, but sufficient to be uncharacteristic of the person when not symptomatic, and are observable by others.

### Antidepressant Medications

#### Classes by Mechanism of Action or Structure

<table>
<thead>
<tr>
<th>Class</th>
<th>Examples</th>

</tr>
<tr>
<td></td>
<td>• Parnate (tranylcypromine)</td>
</tr>
</tbody>
</table>

*TCA*s are Type 1A antiarrhythmic agents which can: increase mortality post MI with PVCs; prolong atrial and ventricular depolarization; lengthen PR, QRS and QT intervals.
Antidepressant Management Tips

- The characteristics of the depressive episode, associated comorbid diagnoses and patient specific factors that influence safety, tolerability, ease of use and cost all influence the choice of antidepressant. Serotonin Specific Reuptake Inhibitor (SSRI) class antidepressants have become the mainstay of initial treatment of MDD, especially in the primary care community, because of their relatively good tolerability and safety profile, and familiarity with the agents. It is important to recognize that other classes of antidepressants may be indicated for depressive episodes with certain features (for example, MAOI class for MDD with atypical features) or when comorbid conditions may also be a target (for example bupropion in MDD and tobacco use disorder), and in cases that do not respond to an adequate trial of an SSRI. Choosing an antidepressant is an exercise in balancing these factors: safety, tolerability, efficacy, price, and simplicity of use.
- It is important to prescribe an antidepressant at adequate dose and duration before considering it a failed trial and switching or augmentation is considered.
- Switching and augmenting have similar rates of efficacy in research trials. Switching may be a less complicated choice in a primary care setting (exceptions being generic triiodothyronine and buspirone, which have few side effects and no significant monitoring demands). Lithium has the strongest efficacy evidence base, but drug interactions and monitoring demands for toxicity, thyroid and renal side effects may be limiting. The atypical antipsychotics (Abilify and Seroquel) have good efficacy data, but also risks for metabolic syndrome and tardive dyskinesia and incur higher cost.
- When switching, typically it is better to switch between rather than within antidepressant class, though some studies have shown that a single switch to another SSRI is an acceptable option.
- Treatment of depression in pregnancy and lactating women requires special considerations that are beyond the scope of this guideline. (See resource section on page 12 in MDD Guideline for further information.)
- All antidepressants: inform and discuss common and potential high-risk side effects including risk of agitation, precipitation of manic episode and/or provocation of suicidal ideation. Most antidepressants should be tapered to avoid a discontinuation syndrome and to give better odds of avoiding a recurrence of depression.
- Patients 24 and younger: highlight risk of provocation of suicidal ideation. The risk of provocation of suicidal ideation (small signal in research studies) must be balanced against the risk of untreated depression (greater risk according to most authorities).

Drug-drug Interactions
It is important to consider potential drug-drug interaction to ensure safe and effective antidepressant prescribing. Both inhibition and induction as well as protein binding effects can result in unexpected and sometimes dramatic differences in expected blood levels resulting in toxicity (e.g., like elevating Warfarin levels or beta blocker levels) or otherwise affecting the effectiveness of the drug. When prescribing antidepressants, it is a best practice to run a drug-drug interaction check using a program such as Epocrates (www.Epocrates.com).

Selected High-risk Antidepressant Side Effects
1. Effexor, Cymbalta and Pristiq: warn about hypertension (check baseline and follow-up blood pressure)
2. Cymbalta: warn about heavy drinking and about pre-existing liver disease (check baseline LFTs prior to prescription if risk factors for liver disease)
3. nefazodone: hepatotoxicity (check baseline and follow-up LFTs)
4. Wellbutrin: seizure provocation (highlight safe dosing parameters)
5. TCA: warn about orthostatic hypotension and overdose risk
6. MAOI: highlight dietary and medication restrictions (For further information, refer to patient education on page 11 in MDD Guideline - MAOI Diet and Medication Restrictions)
MAOI Diet and Medication Restrictions

MAOI class antidepressants are likely underutilized because they are not simple to use, but have indications for MDD with atypical features and in refractory cases. Primary care clinicians typically defer to psychiatric clinicians to determine indications for and management of this class of medications.

When MAOI class antidepressants are used in the treatment of MDD it is important that both provider and patient are informed about dietary and medication restrictions to prevent hypertensive crisis and/or serotonin syndrome. The detail of these restrictions is beyond the scope of this guideline. Readers are advised to consult interaction checking databases when prescribing MAOI class antidepressants.

Dietary restrictions must be observed for at least one day before initiation and two weeks after discontinuation of an MAOI. The duration of medication washout before MAOI initiation depends on the known pharmacokinetic properties of the restricted medication. For example, there should be a two week washout period after most SSRIs before going to an MAOI, with the exception of Prozac for which there is a 5 week washout period. Medication restrictions must be observed for two weeks after the discontinuation of an MAOI.

Common drug interactions of concern include other antidepressant medications, dopamine agonists, carbamazepine, dextromethorphan, disulfiram, meperidine, stimulants and other sympathomimetic amines, and other synthetic narcotics. Over-the-counter medications may present risks, particularly those containing sympathomimetic amines or dextromethorphan. Herbal medications including ginseng, medicinal yeasts and St. John’s Wort are also restricted. Drugs of abuse including cocaine, amphetamines and narcotics are hazardous in conjunction with an MAOI.

The following sources may be useful to readers interested in understanding dietary restrictions which have been refined over the years to be less onerous than they once were:
